Introduction

In the social network era the large scale databases topic is very relevant. The handling of big data such as informations of users and moreover is a critical asset of our society. In fact, from the viewpoint of the security is very important to handle in the correct way this very huge amount of data because, otherwise, it is possible to have leak of critical information that cause critical issues about users privacy.

Another problem caused from large amount of data created from the applications used every day from all of us, is the following: *How we can manage this data?*.

Nowadays we have a lot of tools to do this, the most famous, and maybe the most used, is for sure MongoDB. It allows us to handle a huge amount of data without critical issues and maintaining good performance. Another well-known tool is Neo4J (and so Graph DB) that is in charge of handle the social part of the application, in fact the graph is indeed a network, and so this is the best way to represents a social network where the interactions between users are fundamental and very widespread.

Our aim is to design and implement a modern application which can handle a huge amount of data maintaining good performance and implementing a social network side in order to exploit the desire for social relations of our society.

Chapter 1

Dataset

In this first chapter of this document we will talk about searching for the initial dataset.

As specified in the project documentation, the dataset had to be at least 50MB large, and this quantity could not be generated directly within the application. So we did an initial search, finding two datasets, which were generated by their authors by performing the scraping on the sites www.FoodNetwork.com and www.Epicurios.com. The second dataset was more complete (more nutritional values), so it was used as the main dataset. The other dataset was used to complement the other, reaching a total of 67.8 MB, with 45349 recipes.

To correctly extract the data present in the two datasets we wrote a program in Java, called *RecipeReader*, thanks to which we adapted the two different formats and removed the duplicates (recipes with the same title that were present in both datasets). To implement this program we used the GSon library and the Jackson library.

The variety property is ensured by using two different sources. The velocity / variability properties are ensured because comments and recipes are eliminated and added inside the application, indeed this data may lose importance after a certain time interval since new data quickly arrives.

Chapter 2

Design

2.1 Introduction To The Application

The topic of cuisine is extensively widespread in our society. In fact we can think at the success achieved by tv shows related to cooking in the last years and also at the fact that a lot of chefs are becoming superstars. Then there is another important factor: the coronavirus outbreak.

With the coronavirus outbreak a lot of people became cuisine lovers, in fact at the first moments of the pandemia several ingredients as flour and yeast were very hard to find, because people were confined in their home and so they had more free time.

But this topic is not a recente one. The first recipe book dates back to eight century B.C. and it is the so-called *Eraclio* (by the name of the city in which he was found). Then also an important latin writer, Apicio, wrote one of the most important recipe books of the roman era: *De Re Coquinaria* which dates back to the first century B.C..

So the topic of cuisine is inherent to human nature, because the necessity of eating is a basic need. Furthermore, everyone has experimented the infamous question: "What will I eat this evening?". JustRecipe has the aim of answer to this question, it has the aim of helping university student or workers to retrieve and to do fast and simple recipes.

So this application is basically a recipe book but it is also more than this.

JustRecipe is also a social network which allow people to enjoy, to ex-change ideas about cooking, to feel less lonely in this hard period.

2.2 Requirements

2.2.1 Main Actors

The main actors of the application are four:

• Unregistered User

He is the user which open the application for the first time, in order to access he must sign-up.

• User

He is the normal user (the registered one).

Moderator

He is in charge of controlling the comments and eventually delete the ones which contain abuses.

• Administrator

He is the most powerful actor, he can delete users and recipes and he is also in charge of elect moderators

Each actor can do all the features of the previous ones in the list.

2.2.2 Functional Requirements

Features offered to the Unregistered User

• Registration

In order to access the application an user must sign-up. Otherwise he is not allowed to access and to use all the functionalities.

Features offered to the Registered User

• Login/Logout

The only way to access the application, as we said previously, is to sign-up and login. At the end the user can logout and close the session.

• Search a recipe

It's possible to search a recipe searching for the title and for categories.

• Browse suggested recipes

The suggestions will be offered in a proper section, they are done considering the relationships between the user logged, the users followed by the user logged and so on so forth.

• Browse recipes of following users

In a proper section (i.e. the Homepage) the user can browse the recipes of the following user. Indeed he can see only a snapshot of the recipes. If he wants a more in-depth view, he can click on it and see the recipe page in which he is able to see all the recipe details.

• Add a recipe

The user can insert a new recipe.

• Edit own recipes

The user can edit the recipes previously added by himself.

• Comment recipes

Every user can make a comment about recipes

• Follow another user

The most important feature of each social network: the users can follow each others.

• Like a recipe

In order to evaluate a recipe each user can like its.

Features offered to the Moderator

• Delete comments

The moderator is in charge of delete comments which contain racist abuse, crude terms and so on so forth.

Features offered to the Administrator

• Delete users

The admin can delete the users which don't respect the application guidelines.

• Delete recipes

The admin can delete recipes not correctly inserted

• Elect moderators

In order to handle better the application, the admin can elect some users as moderators.

2.2.3 Non-Functional Requirements

The non-functional requirements of the applications are described in the following lists:

- \bullet usability
- $\bullet \ \ data \ availability$
- Tolerance to single point of failure: if a server crashes another one is available (thanks to replicas). Parlare quindi dell'eventual consistency.
- ullet dire qualcosa sulla sharding
- Reliability
- Security and data encryption???

2.2.4 Actors and Use Cases

The use case diagram of the application is described in the figure 2.1

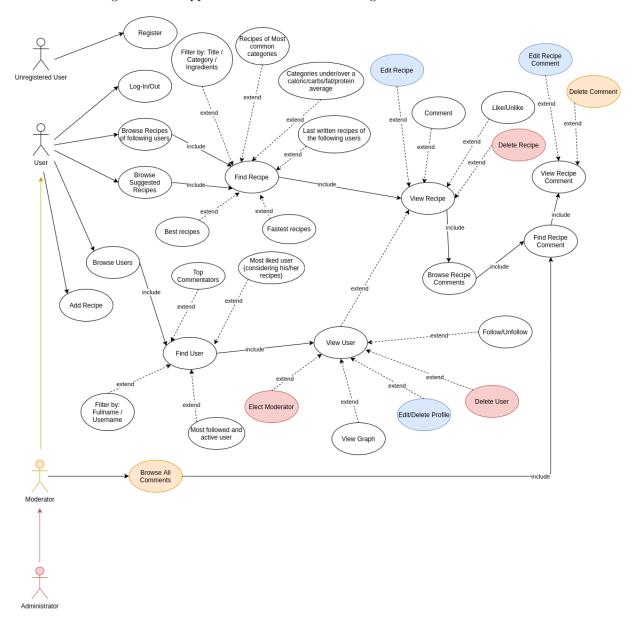

Figure 2.1: Use Case Diagram

Some observations on the diagram are necessary:

- The circles in <u>blue</u> are the ones which described actions available only for the owner of the object on which the actions are applied.
 - So, in detail, this means that a **User** can edit/delete a profile if and only if he owns this profile. Then he can edit a recipe and/or a comment if and only if he adds that recipe or that comment.
- When we are seeing the recipe detail we can go on the user that have been added that recipe. So the extend relation between *View Recipe* and *View User* means this.
- The action Browse Recipes of following users is available only if the **User** follows at least one user. Otherwise he can start to follow users and only after this he can see suggested recipes (Browse Suggested Recipes). In this case, due to the fact that the user follows nobody, he will see the most famous recipes in general because it's impossible to suggest specific recipes due to the fact that he has no following and no likes or comments.

- The actions in <u>red</u> are the ones that can be performed only by the **Administrator**
- The actions in orange are the ones that can be performed only by the **Moderators**

2.3 UML Class Diagram

Let analyze the UML Class Diagram. There are three main entities: User, Comment, Recipe. It's important to point out that the **User** of the Use Case Diagram is here the so-called *Registered User* and the *User* of this diagram is the generic user. Then we undeline the fact that, in order to represent the three actors of the use case diagram, a generalization is needed.

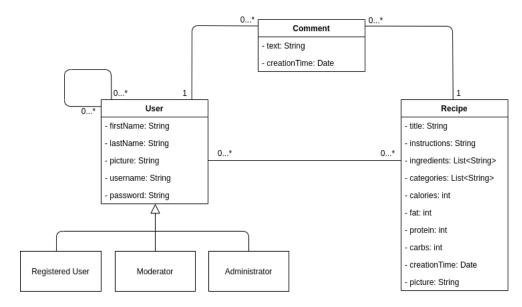

Figure 2.2: UML Analysis Classes Diagram with generalization unsolved

Observing the figure 2.2 it's possible to understand that we can resolve the generalization putting an attribute in the entity *User*. It is an integer and we call it *role*: if it's a *Normal User* role is 0; if *Moderator* then 1; if *Administrator* then 2.

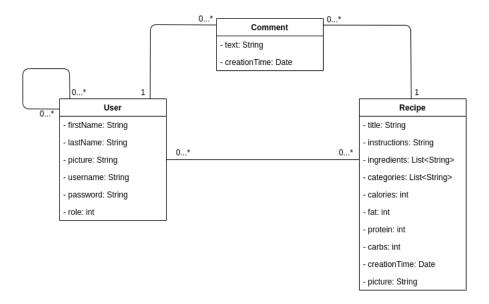

Figure 2.3: UML Analysis Classes Diagram

Classes definitions

Classes definitions:

Table 2.1: Classes definitions

Class	Description
Registered User	A standard user (registered one) who can only perform basic operations
Moderator	User who can also check comments and decide to delete them
Administrator	Most powerful user, he can also delete users and recipes, and elect moderator
Comment	Comment posted by a user
Recipe	Recipe added by one user

Classes attributes

Classes attributes:

Table 2.2: Classes attributes - User

Attribute	Type	Description
firstName	String	First name of the user
lastName	String	Last name of the user
picture	String	URL of the profile picture
username	String	Username of the user (identifier)
password	String	Password chosen by the user, used for the login phase
role	int	Role of the user (0: Normal User, 1: Moderator, 2: Administrator)

Table 2.3: Classes attributes - Comment

Attribute	Type	Description
text	String	Plain text of the comment
${\it creation Time}$	Date	Creation timestamp of the comment

2.4 Data Model

In this section we will discuss about the design choises performed in terms of data model and the databases used in order to handle in the better way our dataset.

2.4.1 DocumentDB

The document DB is used in order to handle the large dataset of recipes that we have. In particular, MongoDB allow us to perform fast query even if the size of the dataset is very big and this is the main reason that brings us to choose it. Moreover it is schemaless and this allow us to maintain etherogenous recipes in our database (some recipes have some attributes, instead others have not those).

Table 2.4: Classes attributes - Recipe

Attribute	Type	Description
title	String	Title of the recipe (identifier)
instructions	String	Operations to be performed to make the recipe
ingredients	List <string></string>	Ingredients to be used in the recipe
categories	List <string></string>	Categories to which the recipe belongs
calories	int	Calories contained in the recipe
fat	int	Fat contained in the recipe
protein	int	Protein contained in the recipe
carbs	int	Carbs contained in the recipe
creationTime	Date	Creation timestamp of the recipe
picture	String	URL of the recipe picture

48
           },....
49
```

2.4.2 GraphDB

The Graph database is the one that handles the social part of the application. Thanks to it we are able to analyze the relationships among users and their recipes. The graph database that we use is Neo4J.

We have two type of nodes within the database:

- User: it is the node that represents the user inside the graph. Its attribute are: firstName, lastName, username, password, picture¹, role².
- **Recipe**: it is the node that represents the recipe within the graph. Its attribute are: *title*, calories, fat, carbs, protein, picture¹

The information about the user are present only on Neo4J because we handle the social part only with it. Instead some information about recipes are present in both databases, in particular on Neo4J we have info that are already present also in MongoDB, but the opposite is not true. The Neo4J relationships are:

- Adds: if the user A has added the recipe R, then we have a relationship :ADDS from A to R $(A \to R)$.
 - We have as property, the one called when that is the timestamp which indicates when the recipe has been added.
- Follows: if the user A has followed the user B, then we have a relationship : FOLLOWS from A to B $(A \rightarrow B)$.
- **Likes**: if the user A has liked the recipe R, then we have a relationship :LIKES from A to R ($A \to R$).

All the relationships that starts from a node X are deleted if X has deleted, furthermore if X is a user, also the recipes that he has added will be eliminated. In figure 2.4 we can see an example of the nodes, the relationships and the attributes.

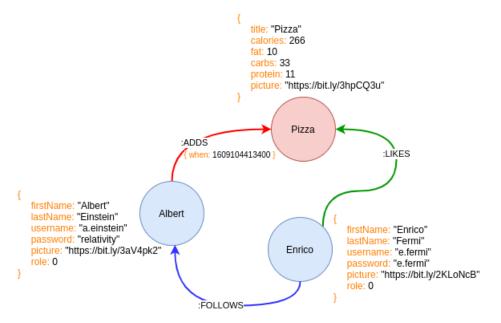

Figure 2.4: Example of Neo4J nodes and relationships

¹Only the URL of the picture is saved in this field, otherwise the size of this attribute would be too large

²0 for the normal user, 1 for moderator and 2 for the administrator

- 2.5.2 Sharding
- 2.6 Software Architecture

Chapter 3

Implementation and Test

3.1 Main Modules

The implementation code is divided into two main modules: RecipeReader and JustRecipe.

- RecipeReader: is a program we wrote to get our initial dataset, extracting the information that interests us from the two initial datasets (see chapter 1).
- JustRecipe: is the actual application, whose implementation will be analyzed in more detail in the next sections. The application was developed following the MVC (Model, View, Controller) pattern. The View displays the data contained in the model and was mainly developed using .fxml files, which allow you to write all the graphic components and their properties in separate files. The Model provides methods for accessing data useful for the application. The Controller receives the commands from the user and implements them by changing the status of the other two components. This division allowed us to completely separate the three components, for a more readable and maintainable code.

3.2 Main Packages and Classes

In this section will be presented the main packages of JustRecipe module and the respective classes.

3.2.1 it.unipi.dii.inginf.lsdb.justrecipe.config

This package is used to handle the configuration parameters, stored in *config.xml*. The schema for the validation is in the file *config.xsd*. The validation is very important to be sure of the correctness of the file *config.xml*.

Classes:

• ConfigurationParameters: this class store all the configuration parameters needed by the application. For example the IP for the Neo4j database. These values do not need to be changed, so only get methods are provided.

3.2.2 it.unipi.dii.inginf.lsdb.justrecipe.main

This package contains the Main class, that starts the application. Classes:

• Main: this class extends Application and implements the start method.

3.2.3 it.unipi.dii.inginf.lsdb.justrecipe.model

This package contains the classes required for the model. These classes are the java bean for our application.

Classes:

- Comment: This class stores all the information about a comment, like the text, the username of the author and the timestamp of creation.
- Recipe: This class stores all the information about a recipe, like the title, the ingredients, and so on.
- *User*: This class stores all the information about a user, like the username, the password, and so on.
- Session: This class is used to maintain the information of the session, like the logged user. We used the singleton design pattern for this class.

3.2.4 it.unipi.dii.inginf.lsdb.justrecipe.persistence

This package deals with managing the persistence of data, in fact it contains the classes used to interface with databases.

Classes:

- DatabaseDriver: this interface declares all the methods that has to be implemented in a database driver. This methods are initConnection() and closeConnection().
- MongoDBDriver: this class implements DatabaseDriver and is responsible for implementing all the queries that have to be run on MongoDB. We used the Singleton design pattern, because a single instance of this driver must be shared by all application classes.
- Neo4jDriver: this class implements DatabaseDriver and is responsible for implementing all the queries that have to be run on Neo4j. We used the Singleton design pattern, because a single instance of this driver must be shared by all application classes.

3.2.5 it.unipi.dii.inginf.lsdb.justrecipe.controller

This package contains the classes required for the controller part of the MVC pattern. For each different page to be shown to the user, a special controller has been implemented, which manages the events resulting from the actions taken by the user and updates the model and the view.

Classes:

- WelcomePageController: this class manages the login/register page of the application.
- HomePageController: this class handles the homepage section of the application (shows the recipes of following users and handles the event, like the click on a recipe snapshot).
- DiscoveryPageController: this class manages the discovery section of the application. So it is in charge of showing the results of search made by the user.
- ProfilePageController: this class manages the profile section of the application. The profile could be either mine or someone else's. Thanks to this class it is possible to manage some events such as following a user, deleting my profile, seeing his recipes, and so on.
- Administration Page Controller: this class handles the Administration section of the application. Of course, not all the users can access to this page, only the moderator (for seeing the last comments) and the administrators (for doing all the possible operations) can access.
- EditProfilPageController: this class manages the page for editing the personal profile. The user can insert a new profile image, change the personal information, and so on. The administrator can change the role of the user in this page.
- AddRecipePageController: this class manages the page of the application used for insert a new recipe.
- RecipeSnapshotController: this class manages the single recipe snapshot, like the click on him.

- RecipePageController: this class handles the page in which we show all the information about a recipe. In this page it is possible also to comment a recipe and see the comments already done.
- CommentController: this class manages the single comment and all the operations that can be done on him.
- *UserSnapshotController*: this class manages the single snapshot of one user, and all the operations that can be done on him.

3.2.6 it.unipi.dii.inginf.lsdb.justrecipe.utils

This package contains a class used to store all the utility functions that we use in the application. Classes:

• *Utils*: this class is used to contain some utility functions used inside the application (to avoid replicating parts of code).

3.3 Most Relevant Queries

In the following section will be presented the most relevant query performed with MongoDB and Neo4J. Some important point must be underlined:

- The operation of *skip* and *limit*, use in the most of the following queries, are necessary due to implementation reasons. In fact the results are not shown all in the same page (because of the size of the database the output can be huge) but only a subset of the result are shown (for instance, the first X) and in order to go on and see the other result, the query will be performed with different value of *<howManyToSkip>* (the first time is 0, the second is X) and *<howManyToGet>* (it's a fixed number, must be equal to the previous X)
- In Neo4J part, due to performance reasons, some queries compute also followers, followings and recipes added by each user. This is necessary because when the user is given as result this information must be showed and if we don't compute it here we have to do another query for each user.

3.3.1 MongoDB

Recipes of the user

This query gives the opportunity to collect all the recipes written by a specific User through checking the author username field. This search is case sensitive cause we are using the username.

- Input: a string who rapresent an username (unique through the users), how many recipe to skip, and how many to get.
- \bullet Output: a list of recipes, all added by the user erlier selected, ordered by the .

```
db.recipes.aggregate (
1
2
     3
          $match :
4
5
6
            authorUsername: <authorUsername>
          }
7
       },
8
9
10
            $sort :
11
12
            creationTime: -1
```

Search for recipe title

Given a portion of the title, this query is capable of returning as a result a set of recipes whose titles contain it. Research must be case insensitive (see *options:"i"* in the regexMatch step of the aggregation)

- Input: portion of the title, how many recipes to skip and how many recipes to get.
- Output: set of recipes.

```
db.recipes.aggregate (
1
     2
3
          $match :
4
5
          {
6
             title:
7
               $regex: /^.*<portionOfTheTitle>.*$/,
8
               $options: "i"
9
10
11
        },
12
13
          $sort
14
15
             creationTime : -1
16
17
18
19
          $skip: <howManyToSkip>
20
21
22
          $limit: <howManyToGet>
23
24
     ]
25
   )
26
```

Search for recipe category

Given the category, or a part of this, the query returns recipes that belong to it. The search is case insensitive.

It's important to point out that a recipe belongs to more than one categories, so a recipe can be part of the result of the search of two different categories (this is normal and it is allowed).

- Input: portion of the category or the entire one *<portionOfTheCategory>*, how many recipes to skip *<howManyToSkip>* and how many to get *<howManyToGet>*.
- Output: set of recipes belonging to the given category

```
db.recipes.aggregate (
2
3
4
          $match :
5
6
            categories:
7
               $regex: /^.*<portionOfTheCategory>.*$/,
8
               $options: "i"
9
10
          }
11
        },
12
13
        $sort:
14
        {
15
          creationTime : -1
16
17
     },
18
     {
19
        $skip: <howManyToSkip>
20
21
     },
     {
22
        $limit: <howManyToGet>
^{23}
24
     ]
25
   )
26
```

Search for recipe ingredients

This query give the possibility to find a specific number of recipes given some of the recipe ingredients. The search is case insensitive for a more easy to use experience.

- Input: a list of ingredients, how many recipes to skip and how many recipe to show.
- Output: a list of recipes, all of them have at least all the ingredients spicified before. The results are ordered from the newer to the older recipe.

```
db.recipes.aggregate (
1
2
3
        $match :
4
5
          ingredients:
6
7
             $regex: /^.*<ingredients[i]>.*$/,
8
9
             $options: "i"
10
11
     },
12
13
        $sort:
14
15
          creationTime : -1
16
17
     },
18
     {
19
        $skip: <howManyToSkip>
20
^{21}
```

```
22  {
23     $limit: <howManyToGet>
24  }
25  ]
26 )
```

Most common recipe categories

This query allows you to get a ranking of the categories most used by users for their recipes.

- Input: how many categories to skip, how many categories to get.
- Output: list with the categories ordered by the number of use.

```
db.recipes.aggregate (
1
2
     3
          $unwind : "$categories"
4
5
        },
6
7
          $group:
8
             _id : "$categories",
9
10
             numberOfRecipes:
11
12
               $sum: 1
13
14
        },
15
16
17
          $project:
18
             'category': '$_id',
19
             numberOfRecipes: 1,
20
21
             _id: 0
22
       },
23
24
          $sort :
25
          {
26
             numberOfRecipes : -1
^{27}
28
29
        {
30
          $skip: <howManyToSkip>
31

Recipes with below average calories - TO DO

Last Comments

The query returns the last comments sorted for creation time, in order to have the most recent as first and the most old as last.

- Input: howManyToGet and howManyToSkip
- Output: set of the last comments sorted by creation time in descendant order.

```
db.recipes.aggregate (
1
2
      E
        {
3
          $unwind : "$comments"
4

Tabella con dominio grafo e descrizione

Suggested Recipes - MANCA CODICE

We have two levels of suggestions with different relevance.

• First Level

Recipe R is a first level suggestion for the user X, if R has been added by the user Y where Y is followed by W who is followed by X ($X \to W \to Y$). Or R has been added by Z where Z is followed by Y ($X \to W \to Y \to Z$).

• Second Level

Recipe R is a second level suggestion for the user X if R has been added by the user Y where Y is the owner of at least N recipes liked by X.

Recipes of following users

This query returns all the recipes of the following users of a specific user.

- Input: How many recipe name to skip, how many recipe name to show and a string who represents a specific username.
- Output: A set of recipe name of the specific user's following users have added.

Most followed and active users

This query returns the list of the most followed and active users, namely the influencers. Most followed means that the list is ordered by the number of followers. Active means that the list is ordered by the number of recipes added by the user.

- Input: How many users to skip, how many users to show.
- Output: A list of the most followed and active users.

```
MATCH (u:User)
1
    OPTIONAL MATCH (u) <- [f1:FOLLOWS] - (:User)
2
    OPTIONAL MATCH (u)-[f2:FOLLOWS]->(:User)
3
    OPTIONAL MATCH (u)-[a:ADDS]->(:Recipe)
4
    RETURN u.firstName, u.lastName, u.username,
5
6
      u.firstName AS firstName, u.lastName AS lastName,
7
      u.picture AS picture, u.username AS username,
      u.password AS password, u.role AS role,
8
    COUNT(DISTINCT f1) AS follower,
9
    COUNT (DISTINCT f2) AS following,
10
    COUNT(DISTINCT a) AS numRecipes
11
    ORDER BY follower DESC, numRecipes DESC
12
    SKIP $howManySkip LIMIT $howMany
13
```

Most liked users

This query returns the list of the most liked users, namely the users who received more like to their recipes.

- Input: How many users to skip, how many users to show.
- Output: A list of the most liked users.

```
1
    MATCH (u:User)
    OPTIONAL MATCH (u)-[:ADDS]->(:Recipe)<-[1:LIKES]-(:User)
2
    OPTIONAL MATCH (u) <- [f1:FOLLOWS] - (:User)
3
    OPTIONAL MATCH (u)-[f2:FOLLOWS]->(:User)
4
    OPTIONAL MATCH (u) - [a: ADDS] -> (: Recipe)
5
    RETURN u.firstName, u.lastName, u.username,
6
      u.firstName AS firstName, u.lastName AS lastName,
7
8
      u.picture AS picture, u.username AS username,
      u.password AS password, u.role AS role,
9
    COUNT(DISTINCT f1) AS follower,
10
    COUNT(DISTINCT f2) AS following,
11
    COUNT(DISTINCT a) AS numRecipes,
12
    COUNT(DISTINCT 1) AS totLikes
13
    ORDER BY totLikes DESC
14
    SKIP $howManySkip LIMIT $howMany
15
```

Best Recipes

This query returns the list of the best recipes, namely the most liked ones.

- Input: How many recipes to skip, how many recipes to show.
- Output: A list of the best recipes.

```
MATCH (:User) - [1:LIKES] -> (r:Recipe)
1
    MATCH (u:User) - [:ADDS] -> (r)
2
    RETURN r.title AS title, r.calories AS calories,
3
      r.fat AS fat, r.protein AS protein, r.carbs AS carbs,
4
      r.picture AS picture, u.username AS authorUsername,
5
    COUNT(DISTINCT 1) AS likes
6
    ORDER BY likes DESC
7
    SKIP $skip LIMIT $limit
8
```

To clarify, the first match is used to avoid to consider the recipes which have not at least one like, and the second match is used to find the user that adds the recipe.

Search for username

Given a portion of the username, this query is able to return all users whose usernames contain it. The search must be case insensitive, so the toLower function is used.

- Input: portion of the username, how many users to skip and how many users to get.
- Output: set of users.

```
MATCH (u:User)
1
    WHERE toLower (u.username) CONTAINS toLower ($username)
2
    OPTIONAL MATCH (u) <- [f1:FOLLOWS] - (:User)
3
    OPTIONAL MATCH (u)-[f2:FOLLOWS]->(:User)
4
    OPTIONAL MATCH (u)-[a:ADDS]->(:Recipe)
5
    RETURN u.firstName AS firstName, u.lastName AS lastName,
6
       u.picture AS picture, u.username AS username,
7
       u.password AS password, u.role AS role,
8
    COUNT(DISTINCT f1) AS follower,
9
10
    COUNT (DISTINCT f2) AS following,
    COUNT(DISTINCT a) AS numRecipes
11
    SKIP $skip LIMIT $limit
12
```

Search for user's full-name

Given the full-name or a part of it, the query returns the users that contains in their full-name the given input. The query is case-insensitive.

- Input: The full-name (\$fullName), how many users to skip (\$skip) and how many users to get (\$limit).
- Output: The users that contains in their full-name the given input \$fullName.

```
MATCH (u:User)
1
      WHERE
2
      toLower(u.firstName+', '+u.lastName)
3
      CONTAINS toLower ($fullName)
4
5
      toLower(u.lastName + ', ' + u.firstName)
6
      CONTAINS toLower($fullName)
7
      OPTIONAL MATCH (u) <- [f1:FOLLOWS] - (:User)
8
      OPTIONAL MATCH (u)-[f2:FOLLOWS]->(:User)
9
      OPTIONAL MATCH (u) - [a: ADDS] -> (: Recipe)
10
      RETURN u.firstName AS firstName, u.lastName AS lastName,
11
       u.picture AS picture, u.username AS username,
12
       u.password AS password, u.role AS role,
13
      COUNT (DISTINCT f1) AS follower,
14
      COUNT (DISTINCT f2) AS following
15
```
